ABSTRACT

Building ventilation is highly used and rated at one of the highest energy consuming categories. Numerous efforts have been done to reduce energy usage and thus the evolution of green buildings. However, the conventional design has generated plenty comfort and health related issues. Stratum ventilation has been studied from 2009 and the potential of the design for thermal comfort is regarded as good compared to existing designs like the ceiling-based or the under-floor design. INTI International University takes part as study field for simulation model to evaluate stratum ventilation for airflow patterns, velocity profile, temperature, relative humidity and also local mean age. A small room (W4m x L5.15m) and a medium size room (W7.85m x L9.2m) has been modelled and simulated with FloEFD software to understand the stratum potential. Prior to that, the flow of air and velocity of air has been determined using design guidelines and standards that limit the design of stratum ventilation. The overall result of the models is acceptable as the thermal comfort when evaluated using the Fanger's Model of PMV-PPD Model. Occupant's breathing zone is evaluated and PMV Index based on ASHRAE Thermal Comfort Tool has shown majority of the occupants are within the cool region between -0.3 up to -1.3. The local mean age of air for medium size room is ranging from 250s to 300s while small room from 60s to 120s. According to the results, the thermal comfort using stratum ventilation in a tropical country is acceptable.

ACKNOWLEDGEMENTS

I would like to take this opportunity to express my deepest gratitude and appreciation to those that has given me so much support along the way. First and foremost, I would like to expressed my thanks to my project supervisor, Prof. Ir. Dr. Yau Yat Huang who has put a lot of effort and providing support and insights that I have helped me towards the end of the project. Deepest appreciation for all the time he has spent to review and advice along this journey.

I would like also like to specially thank Prof. Dr John Lin, in his support and advice that he has given me. Although there was no actual encounter with Prof. Dr John, he has relentlessly provided his professional advice on the new guidelines and simulation results. It is my pleasure to be able to seek his professional guidance in this project that was developed under his supervision throughout the years.

To both my parents, I express my deepest thank you for they have inspired me to be the best I can. When everyone had given up on me, they are my pillars of support. Despite the distance, they are the most important people of my life and I dedicate this to them.

Along this journey, I must acknowledge my dear comrades that have always been supportive as I work through these four years. There is a lot of tears and joy that we shared, and I am grateful for we have been at each other's back when needed. Mr Lai Chien Sin and Mr Ivan Ng have been great team to work with and their relentless support has also been the driving success of today.

I would also like to extend my thank you to Dr. Tezara and Mr Teh for their feedback and their input on this report in the first stages of the project report. I also would like to thank everyone that directly and indirectly helped me throughout this journey.

DEDICATION

I dedicate this to Mr. Sunny Liew for his endless love and support.

CHAPTER 1

INTRODUCTION

1.1. Background

Since the industrial era, the booming development and urbanization addresses climate change as the most pressing environmental issue. A 1-degree of increase in the average temperature has been recorded over the past two centuries and an exponential projection of possible increase of another 3-degrees globally. Climate change is an irreversible phenomenon. All over the globe, there are places with temperature anomalies causing places to be drier, more extreme and wetter than the previous natural temperature. In the tropics, like Malaysia, is often labeled as hot and humid country. Today, tropical equators are drier and weather fluctuates on a diurnal basis. Occurrence of El Nino has caused extreme events to the Pacific Ocean, bringing rain fall and wind current skewed to the east (Tangang, Hsieh and Tang, 1997). With the increase of heat in the urban areas, buildings and skyscrapers are longing for more cooling environment. The cities are crowded in the extremes of the weather, and air is trapped in the between concrete. As temperature rises, circulation of air eventually drops. The demand for energy continues to soar as the need for cooling air increased.

1.1.1. Building Energy Consumption

Commercial buildings are the third main sector contributing to the high record of 7750 GW per year of energy usage in Malaysia (Yau and Hasbi, 2013). Located in the tropical climate regions, the narrow alleys trapped air movement resulting in high urban thermal plume. Energy efficiency is part of green movement to lower energy usage. Thus, never-ceasing effort has been overwhelming many engineers to achieve a balanced system that is eco-friendly, without compromising the development of the cities. In the past, buildings were strategically designed to promote natural ventilation on elevated height. Exemplary buildings like the Menara PJH in Putrajaya and Platinum Sentral have adapted natural ventilation, in support of the green movement.

TM Tower also had taken a step forward in applying under-floor air conditioning to reduce energy consumption. However, due to climate change, high-rise buildings use forced air ventilation and demand greater cooling loads via air-conditioning system.

Efforts have been done to promote change through better cooling devices, innovative designs of systems and integration and manipulating the operation management and control towards green environment (Chua et al., 2013). Considering all factors, better ventilation encourages better health and simultaneously a more sustainable energy use. Air-conditioning ventilation that is widely used is the overhead ventilation (OHAD) and under floor air distribution (UFAD), that constantly require high-energy consumption to cool air. A discovery of a new ventilation system, stratum ventilation method has been investigated and implemented in the subtropical regions like Hong Kong and China.

1.1.2. Potential Ventilation System

Stratum ventilation is potential in providing good thermal comfort and also very energy efficient. Various simulation scenarios have been studied to demonstrate that the ventilation system is effective in delivering desired results for all types of consumers of sedentary or mobile occupants. The stratum ventilation has proved its feasibility for buildings in subtropical region, where average temperature is 23.3 degree Celsius and mean humidity of 76%. For this study, comparing to tropical country alike Malaysia of average temperature, 28 degree Celsius and relative humidity of 80% on a daily basis as illustrated in Figure 1.1. The stratum ventilation is reinvestigated to validate the feasibility of such design in a hot and humid climate.
