## NON-PLAGIARISM DECLARATION

By this letter I declare that I have written this thesis completely by myself, and that I have used no other sources or resources than the ones mentioned.

I have indicated all quotes and citations that were literally taken from publications, or that were in close accordance with the meaning of those publications, as such. All sources and other resources used are stated in the references.

Moreover I have not handed in a thesis similar in contents elsewhere.

In case of proof that the thesis has not been constructed in accordance with this declaration, the Faculty of Health and Life Sciences has the right to consider the research thesis as a deliberate act that has been aimed at making correct judgment of the candidate's expertise, insights and skills impossible.

I acknowledge that the assessor of this item may, for the purpose of assessing this item,

- reproduce this assessment item and provide a copy to another member of the University; and/or,
- communicate a copy of this assessment item to a plagiarism checking service (which may then retain a copy of the assessment item on its database for the purpose of future plagiarism checking).

In case of plagiarism the examiner has the right to fail me and take action as prescribed by the rules regarding Academic Misconduct practiced by INTI International University.

(SUPERVISOR)

## ACKNOWLEDGEMENT

First and foremost, I would like to thank my supervisor, Dr. Choong, for the motivation and guidance throughout this research. Despite his busy schedule, he managed to oversee my research progress until the completion of this research. Without the help and support, this research may not be able to be completed in a limited amount of time.

Besides, I would like to thank my family and friends for the support and motivation. In addition, I would like to thank my lab mates Er Vin, Efendy Chew, and Eric Chuah for the accompanying throughout this research. Without them, doing research in the laboratory would never be the same. Not forgetting my examiners of this research, Dr. Wong Kok Kee and Dr. Thong Weng Hing, for their efforts made while providing suggestion on this dissertation. Last but not least, I would like to thank the lab assistances, Ms. Quah and Mr. Ng, for being patience while fulfilling my constant request for laboratory apparatus.

## ABSTRACT

Carnivorous plants are generally uncommon and some of the species are endangered. These plants have the most unusual adaptation to survive in environment that is nutrient deficient by capturing preys. Hence, propagation is required to prevent the extinction of these species. *In vitro* propagation could mass propagate the species to address the problem. Somatic embryogenesis (SE) could produce higher number of propagates. Besides, SE is studied to understand similar process of zygotic embryogenesis. The purpose of this research was to look for cellular and molecular markers during the early events of SE. Explants of *D. burmannii* and *D. tokaiensis* were subcultured on a medium supplemented with thidiazuron to induce SE. Explants were sampled based on different incubation period where day-0 sampling served as negative control. Major events that occurred from the transition of induced cells into somatic embryo, and up to globular structure were investigated using histology. Specific primers targeting EF1 and GAPDH were designed from previous isolated sequences from *D. tokaiensis*. Degenerate primers were also designed from downloaded database sequences. RT-PCR was performed using the designed specific and degenerate primers followed by sequence analysis. Isolation of SE induced cells from their surrounding was observed. Early events leading to the formation of globular structures in epidermis cells reconfirmed a previous study, which was documented alongside some new findings elaborated in the Results section. SE from induced mesophyll cells proposed previously was documented in this study. Specific primers targeting EF1 and GAPDH genes successfully amplified their target sequence and could be used for quantitative PCR (qPCR) in future. ACT and SERK1 sequences were isolated and could be used for designing qPCR specific primers for detection of SE in *D. tokaiensis*. SERK1 gene could be used for early detection of SE while ACT, EF1 and GAPDH could be used as a normalisation in qPCR. Findings obtained in this research facilitate deeper understanding of early development of SE and SE regeneration pathway could serve as a reference to provide understanding in other plant species.

## CHAPTER 1

### INTRODUCTION

Conservation is paramount to conserve endangered or soon to be endangered species. A wide range of wildlife species are included in the CITES Appendices, lists of species compiled based on how threatened the species are, extending to many prominent species which include carnivorous plants (CITES, 2013). Carnivorous plants have the most unusual adaptation to survive in an environment that is nutrient deficient. Most plants obtain their nutrients from soil whereas carnivorous plants obtain extra nutrient supply through carnivory. Their leaves have the ability to trap, digest and absorb the nutrients from their preys therefore decreasing their dependence on photosynthesis (Król et al., 2011). Carnivorous plant is generally uncommon, therefore illegal poaching and destruction of its natural habitat through urbanisation, agriculture, and forestry are threatening the population of carnivorous plants (Botanical Society of America, 2012; IUCN, 2015). Hence, carnivorous plants should be conserved to prevent extinction of these wonderful species and one of the approaches is through plant propagation.

Plant propagation is a cultivation technique which involves in production of plants using different initial materials such as leaves, roots, stems, or other explants. Propagation techniques include *in vitro* propagation and conventional propagation (Bareja, 2010). *In vitro* propagation is able to produce large number of plantlets in a sterile and disease-free environment and provides essential nutrients for the plantlets to grow (Fay, 1994). In addition, *in vitro* propagation is preferred as the propagation can be controlled with the use of growth regulator and favourable environment (Bhojwani & Dantu, 2013).

There are two regeneration modes in *in vitro* propagation, namely somatic embryogenesis and organogenesis. Somatic embryogenesis is a development process to generate somatic embryos from somatic cells under appropriate conditions. Meanwhile organogenesis in plant produces plant organs, mainly shoots and roots, induced by plant growth regulators. Somatic embryogenesis enables production of

large number of plantlets when induced and the process does not require high labour force compared to organogenesis (Bhojwani & Dantu, 2013). In addition, plantlets derived from somatic embryogenesis are lesser in variation among each other; in contrast, organogenesis are more prone to undergo mutations and epigenetic changes (Tsukaya & Beemster, 2006). However, problem faced by many plant biologists was that growth and development of cells and tissues that occurred in a short span of time was unable to be observed with naked eyes especially during certain embryogenesis stages (Sia, 2015). Somatic embryogenesis can be recognised if specific cellular or molecular cues are detected.

Plant anatomy is important in this research to recognise and determine the developmental events which occurred inside the plant at different stages and to provide a better understanding of relationship between the expression of gene and biological events during the developmental process of somatic embryogenesis (Yang, & Zhang, 2010). Developmental events can be determined by comparing cellular structure and morphology with cellular marker (Arnold, Sabala, Bozhkov, & Filonova, 2002). These developmental events provide an in-depth understanding of mechanisms required during the transition into embryos in term of biochemical, morphological and cellular structure (Kurzynska et al., 2012). Hence, histology approach plays a role in this research to observe the difference between the explants at cellular level sampled at specific intervals.

During the early stage of embryogenesis, it was proposed that there were two possible pathways of embryogenesis (Sia, 2015). One of the pathways was described in detail with evidences but the other pathway lacked sufficient information to describe the transition of somatic cells into somatic embryos. More samplings should be done to reconfirm these previous observations and discover development stages not reported previously. The more complete the regeneration model of selected carnivorous plants, the better it can be used for somatic embryogenesis detection.

Another approach which complements histological approach is via molecular detection of somatic embryogenesis-related gene expression in developing explants and embryos (Chugh & Khurana, 2002). Previous study by Nor Farrah Wahidah (2015) found that elongation factor gene expression was the highest at day 28 where
